e-mail: r.s.laramee@swansea.ac.uk

Abstract

This paper attempts to explain the mechanics of writing a research paper in visualization. This serves as a useful starting point for those who have never written a research paper before or have very little previous experience. After all, no one is born knowing how to write one. And yet, there are certain elements, a commonality, that should be found in virtually all good visualization research papers. We give our recommendations as to each section a good research paper consists of as well as what each section contains. This manuscript itself follows our recommended structure.

We believe that paper writing should start with the abstract. The abstract can be approximately 6-12 sentences. It's a difficult starting point, but it forces the author to write down a concise description of what they're researching and what the benefits are. Chances are, if the author can't start out by writing an abstract, then it is not clear in the author's mind what the paper should be about. Of course the abstract will be refined and updated during the paper writing process. The abstract should concisely (1) identify the research topic, (2) describe the novelty of the presented work, and (3) identify the benefits and advantages that result.

Categories and Subject Descriptors (according to ACM CCS): K.3.2 [Computer and Information Science Education]: Computer Science Education

1. Introduction (Motivation)

"Give a man a fish; you have fed him for today. Teach a man to fish; and you have fed him for a lifetime."—Lao Tzu (Chinese proverb).

This quote summarizes the idea behind this paper. It strives to serve as a fishing rod, or at least partially, for those new to writing research papers. These brief guidelines are meant to serve as a *starting* point to those (most likely students) writing a research paper for the first time. The idea was inspired by some new PhD candidate students studying visual computing and preparing their first research paper(s). Writing a good visualization research paper is difficult, yet, students are given this task with little or no instruction. We felt a strong need to at least provide the student with some

written guidelines to start with, which, to the best of our knowledge, do not exist.

Here, we go through section-by-section, those components that we believe a good research paper, in general, contains. We give general informal guidelines on the contents of each section as well. We describe the *Introduction, Related Work, Method, Implementation, Results, Conclusions and Future Work*, and *Acknowledgements* sections. We also provide recommendations on paper titles, temporal planning, literature searching, collaborations, diagrams, figures, images, enhancements, application papers, proof-reading, and references. Several citations to examples are provided for reference. We keep in mind that these topics are rather subjective and our discussion of each topic is driven by experi-

ence. The result is only meant to serve as a rough guideline and a useful starting point. There is no substitute for experience or an experienced advisor. This paper itself is structured according to our recommended guidelines.

Although the title of the starting section is “*Introduction*” it should really be *Motivation*. Quickly, in one or two sentences, introduce the topic. This is followed immediately with *why* this is a useful research direction, including possible applications of the presented research. “*What is this research topic good for?*” is really the question a good introduction attempts to answer. See Chen et al. [CLZ07] for a good example of motivating the presented research.

After the motivation behind the subject is described, the novelty, benefits, and advantages of the research are described. Remember, this is actually where a research project often starts. It begins with an idea, and one key to evaluating how good an idea is being able to identify its novelty and advantages. Each contribution and each benefit that reading this paper provides is identified very explicitly in a bulleted list. Possible points to mention include:

- Does the presented algorithm(s) provide a novel visualization of some sort? i.e., images never before seen.
- Does the presented work provide new interaction techniques not previously published?
- Does the technique described result in faster performance times than previous algorithms and if so why?
- Does the approach provide new insight in some way?
- Does the work take advantage of the graphics card hardware in some way? For example, using texture-mapping hardware, or hardware-accelerated interpolation?
- What are the contributions, precisely, of this paper? What does the reader potentially gain from this paper?

Words like, *contribute*, *novel*, and *advantageous*, are used in this list. An explicit bulleted list should be used in order to make the subject black and white to the reviewer, otherwise, a reviewer might not understand the contribution described. See Chen et al. [CMLZ08], Garth et al. [GLT*07], Laramée et al. [LJH03], and Zhang et al. [ZYZL09] for good examples of such lists of contributions.

The presented work normally builds on a previous algorithm. If so, your work should inherit benefits from the previous work. Those inherited advantages inherited may also be listed. See Grabner and Laramée [GL05] for a good example of a bulleted list of inherited benefits.

In order to achieve the amazing benefits your research results have to offer, specific challenges must be overcome, both conceptual and technical. Those challenges can be mentioned here very briefly.

The introduction section then concludes with how the rest of the paper is organized. Section 2 presents previous work on this topic. Section 3 presents the method starting with an overview. Section 5 describes some unexpected aspects of the our model necessary for a successful implementation.

Section 6 presents our results both visual and from a performance point of view. Section 7 addresses application papers. Section 8 completes the exposition with conclusions and future work.

On Paper Titles: Regardless of the title of your paper, in general it will informally be referred to using two to three words. For example, “*Marching Cubes: A High Resolution 3D Surface Construction Algorithm*” is simplified to “*The Marching Cubes*” paper [LC87]. “*Visual Analysis and Exploration of Fluid Flow in a Cooling Jacket*” becomes “*The Cooling Jacket*” paper [LGD*05]. On one hand, the title of your paper should ideally be simple enough such that it can easily be remembered and identified with two or three words. On the other hand, a title should also be long enough in order to convey some sort of helpful meaning and description to the reader. This problem can usually be resolved using a **title:subtitle** combination, as in the case of *Marching Cubes* [LC87] (no pun intended).

On Temporal Planning: We believe a high visibility publication requires approximately two months to write. A good, complete first draft takes about one month to write. During the second month the paper can be improved with approximately four rounds (or more) of iterative feedback from a co-author(s). Taking this point of view, paper writing should start about two months before the proposed deadline. Extra time can be allowed for non-native speakers.

On LaTeX: In our opinion, the best software for writing papers is \LaTeX . \LaTeX produces high quality, professional-looking output. Virtually all conferences and journals provide \LaTeX templates for paper submissions. We encourage unfamiliar readers to explore this software. Kopka and Daly provide an excellent \LaTeX reference guide [KD04].

2. Related Work

The Related Work Section is actually what makes a research paper a research paper. It demonstrates to the reader that you have done your homework, reviewed the previous literature, and now are ready to present a new contribution over what has been previously published.

One of the difficult aspects of the related work section is choosing the proper scope, e.g., how many related papers to include and which ones. For new authors, this is something an advisor can help with. In short, each previous publication gets a 2-3 sentence description. In the description it is made clear to the reader how the presented work (this paper) is different (better) than the previous piece of literature.

It is important to note that there is some subjectivity in choosing which papers to refer to and also importantly, which previous literature not to refer to. In particular, the references contained in the paper may influence who is chosen to review the paper. Some senior reviewers, papers chairs, or

editors may choose reviewers based on the authors appearing in the list of references (a logical and common method). This means that you as a writer may also influence (but by all means not deterministically) who ends up reviewing your paper. Given a complete list of references, a sub-set of them can be considered mandatory and some can be considered optional. Thus some authors use the optional references to influence who will review the paper and perhaps will also try to steer away from certain reviewers.

When referring to previous work use names, not only numbers (or initial letters). So, instead of writing, “In [JL97], an algorithm for the creating of evenly-spaced streamlines is presented.”, write, “Jobard and Lefer present an algorithm for creating evenly-spaced streamlines [JL97].” The names are much more helpful to the reader than the numbers alone. Also, the previous literature was written by real people whom, in the best case scenario, you will actually meet at a conference. Writing the names also shows a certain respect and appreciation for the previous work that numbers alone do not.

Incidentally, this paper also has related literature. Smith describes how a manuscript should be refereed [Smi90]. Lee presents another interesting paper on how to review a research paper [Lee95]. Cetintemel has written an excellent article about how to conduct an academic job search targeted at computer scientists [Cet01]. Globus and Raible have written a great how-to-cheat when writing a visualization paper [GR94]. Munzner [Mun08] provides a nice overview of ways to prevent an information visualization paper from being rejected from the review process. We note this this paper is targeted mostly towards scientific visualization papers, however, we believe it is also a helpful starting point for those preparing information visualization manuscripts.

On the Literature Search: For a visualization paper, the basic previous literature search consists of looking through the previous 10 years of (1) the IEEE *Visualization* conference proceedings, (2) the IEEE *Transactions on Visualization and Computer Graphics* (IEEE *TVCG*) journal papers, and (3) the *EuroVis* conference proceedings (called *VisSym* until 2005). In principle it’s simple, but it is time consuming. From these three publication venues basically all other related work can be found by looking through the references of the related papers found in the three aforementioned publications. First, prospective related papers are found by reading the titles. After candidates are found based on titles, then their abstracts should be read. After candidates are found based on abstract, then the full papers should be browsed.

It’s also important to look for survey papers and state-of-the-art reports. Very helpful state-of-the-art reports are published every year at the EUROGRAPHICS conference and also in the *Computer Graphics Forum* journal. There’s also a chance that a related survey paper has been published in the *ACM Computing Surveys* journal.

The literature search is an educational process. If you find hundreds of previous papers that appear to be related to the chosen topic, this may be a warning sign. For example, if you chose to work on isosurface rendering, then you would, in fact, find hundreds of previous papers on this topic. That means that this is already very well researched. Thus the chances of making a contribution in this area with impact are reduced. (We learned this the hard way [LB02].) It’s better to find a topic with a more manageable, preferably small, amount of previous literature. How to *read* a research paper is another topic [Lar07].

On Collaborations: Collaborators are good for filling in the gaps when you suspect that there may be holes or an absence of knowledge somewhere. We think that collaborations, in general, have a tendency to increase the quality of a paper. Also, we find collaborations one of the best ways of learning new things and for networking.

3. Method (or Computational Model)

Section 3 is the main content of the paper and thus occupies the most space. It starts with an overview (Section 3.1) followed by the details of each component of your system or each stage of your method, e.g., Section 3.2 and so on. The name of Section 3 could be the name of your algorithm (if it has a name, e.g. Image Space Advection (ISA) [LvWJH04]). Section 3 could also be called just *Method* or *Computational Model*. It presents an idealized model or process by which your algorithm or system works (or how it should work).

3.1. Method Overview

The description of any system or algorithm should start out with an overview before jumping into the details. An overview should include an overview diagram like that of Figure 1. The method overview diagram depicts the *conceptual model* that the algorithm or system in this paper follows. This is not to be confused with its implementation. Of course there is a correspondence, however, a single concept has potentially many different implementations. This subsection focuses on the concept. Other subsections that follow like Sections 3.2 and 3.3 can describe implementation details, including pseudocode. See Chen et al. [CMLZ08], Laramee [Lar03], and Schultz and Seidel [SS08] for examples of pseudocode describing the method. One nice property of Schultz and Seidel’s pseudocode is that it fully describes the input and output of the algorithm.

Section 3, like paper writing, can follow a divide-and-conquer approach. Just as a paper is divided up into sections, Section 3 can be broken down into subsections—starting with an overview diagram. Each subsection in Section 3 can then correspond to a component of the overview diagram.

See Gyulassy et al. [GBHP08], Jobard et al. [JEH01], Laramee et al. [LJH03, LvWJH04], Spencer et al. [SLCZ09],

Figure 1: Method Overview. An overview diagram illustrates the conceptual model your algorithm implements. Figures should be placed at the top of the page by default. This figure was made using Xfig. Inkscape is another good, open source tool for producing diagrams.

and Van Wijk [vW05] for good examples of overview diagrams. Gyulassy et al. [GBHP08] provide a really nice diagram that exploits computer graphics in order to provide a concise step-by-step algorithm guide. See Laramee et al. [LHD*04] for overview diagrams used in a state-of-the-art literature survey.

3.2. Stage 1

For each stage or component of your system or algorithm there should be a corresponding subsection in Section 3 providing further details to the reader. Subsections themselves may contain further diagrams, illustrations, examples, and pseudo-code.

3.3. Stage 2...

A description of the next component in the presented algorithm or system (from Figure 1) is presented here.

3.4. Parameters

Any new algorithm ultimately introduces new parameters, e.g., threshold values, alpha values, special distances, minimum and maximum values, etc. Identifying and discussing these new parameters is a good idea. Illustrating the effect of setting these parameters to a range of different values is instructive and helps the reader gain an understanding of the

algorithm or method being presented. In fact, during any implementation, the best value of any new parameter is generally unknown. Thus it is best to implement them as user options since their value may change depending on the data set being evaluated. After a thorough testing phase, the new parameter may be given an optimal default value. See Jobard et al. [JL97, JEH01, JEH02], Van Wijk [vW02], and Telea and Van Wijk [TvW99] for good example discussions of new algorithm parameters.

3.5. Figures and Images

Figures, images and their captions should be “self-contained”. By self-contained, we mean that the reader should be able to look at any figure or image, read its caption, and gain a basic understanding *without* having to read the main text. Enough details should be provided in the caption such that the reader is not required to read the whole paper in order to understand an image or figure. Many reviewers (and readers), will make a first pass through a paper simply by flipping through the pages, looking at the images and captions, and already gain an impression of the paper. This first pass may already influence the final reviewer’s opinion and thus the outcome of the review. If the reviewer appreciates the images and can gain an understanding of them from the captions, they may form a favorable first impression of the paper. This is true about readers in general and does not only apply to research papers. When a potential reader picks up any reading material, whether it be a newspaper, magazine, or book, they first flip through it to look at the pictures. If they find an interesting picture, they read the caption. If they find interesting pictures and captions, they may then go on to read the main text.

Figures and images that show new visualizations are very good to include in a visualization paper. In fact, that is a major goal. If an image really shows something new, then it’s probably a good figure to include. Pedagogic figures are also good. On the topic of figure quality, probably only experience from reading other papers can help in judging the proper level of quality.

The author will make his job easier if makes all of his images, e.g., screen shots or frame buffer images, the same resolution, perhaps through a user setting. Also, a user setting that changes the background color to white is very useful. Images with a white background are best for papers in our opinion. We refer the reader to Tufte [Tuf83] for further stylistic guidelines.

4. Enhancements (or Extentions)

After the main details of your research method are presented in Section 3 a follow-up Section may be added that includes enhancements or extentions to the basic algorithm. There may be a subsection for each enhancement or extention. See Jobard et al. [JEH02], Jobard and Lefer [JL97], and Turk and

Banks [TB96] for examples of this. Enhancements or extensions don't have to be a separate section of the paper. They could be subsections of Section 3.

5. Implementation

This Section is more-or-less optional. It describes the implementation of your model from Section 3. In particular, it describes aspects of your model that are *unexpected*. In other words, during the implementation of the computational model, what things came up that were unexpected. What had to be implemented in order for the model to work? Was the implementation more difficult than expected? Or is it easy? Sometimes the implementation details are also integrated into the corresponding method sub-sections. See Laramée et al. [LJH03] for a sample Implementation section.

6. Results and Performance

The Results and Performance Analysis Sections can be separate, but they are often lumped together in the same Section. If the performance analysis is more extensive it can be put in its own section. Separate sub-sections are also logical.

6.1. Results

In this section, the nicest images of your algorithm are presented to both synthetic and real-world data sets. The (new) insight provided by the visualization is described. A concise description of the data set the algorithm is being applied to is also described. The following characteristics of the data sets should be given: (1) what the data sets are and perhaps what domain they come from, (2) how large the data sets are—or their resolution in the case of structured data, (3) the spatial and temporal dimensionality of the data sets should be given, and (4) whether or not they are represented by structured or unstructured grids and (5) if they are multiresolution or adaptive resolution data samples.

Hopefully, you'll be able to show your algorithm being applied to data sets from another domain, e.g., the visualization of simulation data, in order to demonstrate that your algorithm actually works in general.

6.2. Performance Analysis

In visualization (and computer graphics) there's always a trade-off between quality (or accuracy) and speed (or memory and speed). Generally, the faster the performance, the lower the quality. The algorithm or system being presented should have some free parameters that can be adjusted to trade off quality for speed and vice-versa. Essentially, *every* parameter whose value you are not sure of should be a user-defined parameter—an option that can actually be changed by the user at run time (not just compile time).

Remember, visualization is used for analysis, exploration,

and presentation. For presentation, the image quality must be at its highest, and thus performance probably at its slowest. The highest quality is used to generate the images for the paper, presentation, and videos. For exploration, the algorithms and systems are tuned for the fast performance times possible. All optional enhancements should be turned off (unless your algorithm always runs at interactive frame rates).

A table of performance times can report both aspects, optimized for speed, i.e., exploration mode, and optimized for quality, i.e., presentation mode. The best and most honest reports of performance times will show when the algorithm or system reaches its limits, e.g., when it starts to run slow due perhaps to large data sets. Algorithms also usually trade off memory for speed. In other words, faster algorithms often require more memory, basically because more calculations are pre-processed and stored. Unfortunately, these limits are often left out of visualization research papers.

See Laramée et al. [LB02, LJH03, LvWJH04], Peng and Laramée [PL08], and Spencer et al. [SLCZ09] for examples of detailed performance analysis that trades off between performance and quality or memory and speed.

7. Application Papers

An application paper presents the contribution of visualization techniques toward the understanding of application-specific data. This class of paper examines and discusses the effectiveness of the visualization methods for a particular application. In other words, an application paper describes how known, off-the-shelf visualization techniques have been used (and possibly adapted) to study a domain-specific problem. It is not essential to present original visualization techniques. Although there is overlap, in terms of content and layout, with research papers, there are also differences.

Section 1, the *Introduction*, is very similar for an application paper. It provides the motivation for studying the topic at hand.

Section 2, *Related Work*, is also very similar to a normal research paper. However, in the case of an application paper, there are also additional related research papers from the application domain being studied. For example, if the application paper studies a problem from the biological sciences, then the related work section may also contain references from the biological sciences that may not normally be featured in a visualization research paper.

An application paper may contain an additional Section 3, *Background*. The Background section may describe some pre-requisite knowledge stemming from the application domain being studied. In other words, the Background section may provide information not presumed to be known *a priori* to a typical computer scientist, but may be well-known to a scientist from the application domain. One of the important roles of the Background section is to describe explic-

itly the questions that the domain-specific scientist is trying to answer when carrying out their work. See Laramee et al. [LSH04, LWSH04, LGD*05] for examples of these types of questions.

Instead of the *Method* section found in a research paper, an application paper contains a *Visualizations* section. The Visualizations section describes and presents all of the visualizations that were applied to the domain-specific problem. It also details the additional advantages or insights that each visualization has to offer over previous studies of the same problem. Often, other disciplines will use simple visualizations to study their data such as time-series plots, 2D scatter plots, and bar charts, etc. The Visualizations Section illustrates the advantages of your techniques over the traditional, simple visualizations. The Method section should also carefully describe how a particular visualization technique has been adapted to be suitable to the problem at hand. See Scheuermann et al. [SBH99] for an example of this.

Instead of the *Results* section normally found in a research paper with a traditional performance analysis, an application paper presents a *Domain Expert Review* section. See Grundy et al. [GJL*08] for an example of domain expert review. The two most common criticisms of an application paper are that (1) no additional insight is provided by the visualizations used by the author (over those used previously) and (2) no feedback has been given by an expert from the application domain. Domain expert feedback is an essential ingredient in an application paper. The visualizations must be shown to a domain expert and the domain expert should provide some feedback.

The remaining Conclusions and Future Work sections are similar to a research paper.

8. Conclusions and Future Work

The Conclusions section simply summarizes both the novelty of the presented work and lists the resulting advantages. Remind the reader why the presented work is so good and what's new. Basically, it's like a concise, one-to-two paragraph summary of the abstract and introduction sections.

The future work should be short. Generally it's about three sentences of possible future extensions to the presented work. If you're not sure what to write, it's almost always possible to include a GPU-centered version of the presented work. Extending the visualization to a higher dimensionality is also often a future work project.

Example: We have presented the essentials to writing a research paper in visualization. Although every research paper is different, there is some commonality that can be found in all good research papers. Here we attempt to identify that commonality and describe the essential necessary ingredients of paper sections and their contents. Several example research papers are cited for reference. The result is meant

to serve as a starting point for those with little or no experience in writing research papers. Writing research papers is both an art and an engineering exercise and no one is born knowing how.

Future work includes writing an HCI version of this paper and writing a more general version that applies to computer science research papers.

9. Acknowledgements

The Acknowledgements section thanks any agency or organization that may have contributed funding to the presented research, e.g., the EPSRC, KPlus, the NIH, the NSF, etc. This section also mentions any people that may have contributed in some way, e.g., with the implementation or with discussions or feedback.

Thanks to Ben Spencer of Swansea University for providing the impetus behind this paper. Thanks also to Eugene Zhang of Oregon State University for his valuable feedback. We thank Edward Grundy of Swansea University for his help in proof-reading the manuscript. We thank all of our previous co-authors, especially R. Daniel Bergeron of the University of New Hampshire, Durham, Colin Ware also at the University of New Hampshire Durham, and Helwig Hauser at the University of Bergen, Norway, for teaching us how to write a research paper.

There is one other thing the Acknowledgements Section can be used for and that is to thank potential reviewers. If you have a strong suspicion about who will end up reviewing your paper, then it does not hurt to put this person's name in the Acknowledgements Section and thank them in some capacity. See Laramee et al. [LSH04] for an example of this used in practice. The first author basically knew that Van Wijk would be a reviewer of that paper and acknowledged his contributions before the review process.

Questions, comments, suggestions for improvement, contributions to this paper, or any other feedback is not only welcome but encouraged. Please contact the first author.

On Proofreading: In the ideal world, a paper is proof read by someone outside the project the day before submission to look for small typographical errors. This manuscript has gone through this process. Fresh new eyes that don't necessarily know the topic can be good for spotting these things, at least in our experience.

My former advisor, Helwig Hauser, helped me out one day by proof-reading a paper I had been working on [LW02]. The version of the manuscript he reviewed had mistakes in the references—comments left behind by accident. My advisor pointed out the errors by saying, “Bob, ...you know some people, for example reviewers, *start with the references* when reading a paper, looking them over very carefully”. I thought to myself, “What kind of anal-retentive geek does that?”

I have turned into one of those people. Whenever I review a paper, I start by detaching the references from the rest of the paper and laying them aside, making it easier to check them as I read through the paper. References should be accurate and complete, i.e., with page numbers etc. A paper without complete and correct references can leave a bad impression on the reader and detract from the paper's credibility. Errors can be interpreted as sloppy and also be a sign of hastiness.
